

Reliability of statements about smoking habits

Report on ACS Follow-up Study

Authors: Mrs.B.A.Forey and P.N.Lee  
Date : 15.5.86

## SUMMARY

### Methods

In 1980, a representative sample of 8,600 U.K. subjects aged 16+ were interviewed about their own smoking habits and those of other members of their household, information on certain demographic characteristics also being obtained. Subsequently, in 1985, 540 of the 5,289 subjects aged 25-65 in 1980 were reinterviewed. The second questionnaire repeated the main questions on own smoking and also asked subjects to recall their own habits in 1980.

### Objectives

The main objective of the study was to assess consistency of statements made in 1980 and 1985 in response to a series of identical questions which allowed classification of subjects as never smokers, ex-smokers and current smokers.

Subsidiary objectives were:

- (i) to assess the level of concordance between the subject's own smoking habits and those of his or her spouse and those of other household members,
- (ii) to assess how good 1985 recall of 1980 smoking habits was and how this recall varied according to current smoking habits,
- (iii) to compare memory of events prior to 1980 in the 2 surveys,
- (iv) to assess changes in habits between 1980 and 1985 and to which factors the changes related.
- (v) to compare results with those reported earlier in Research Papers 2 and 2A.

### Concordance of smoking habits

Husband's and wife's smoking habits in 1980 were strongly correlated, with current manufactured cigarette smokers 2.7 times more likely than never smokers to have a spouse who smokes manufactured cigarettes.

The number of other smokers in the household is strongly correlated with the subject's own smoking habits.

### Consistency of statements made in 1980 and 1985

After taking account of occasional smokers, 14.8% of men and 3.6% of women, who in 1985 stated they had never smoked, had earlier stated they were current or ex-smokers. (Type I inconsistency).

In addition, 22.0% of men and 7.8% of women, who in 1980 stated they had never smoked, later stated that they were current or ex-smokers and had started to smoke before 1980. (Type II inconsistency).

Both Type I and Type II inconsistency were more frequent in older subjects and in subjects whose two statements about age were inconsistent.

Compared with consistent smokers, both inconsistent groups reported having smoked for fewer years. Where the inconsistency was between being a never and ex-smoker, the stated time of giving up was longer ago and the number of manufactured cigarettes smoked at the time of giving up less than in other ex-smokers.

The proportion of Type I inconsistent subjects who reported in 1980 that their spouse smoked was about the same as among consistent smokers. However, among Type II inconsistent subjects, it was lower even than consistent never smokers.

There was also 1 man and 1 woman, who said they were current smokers in 1980 but who in 1985 claimed to have given up before 1980. (Type III inconsistency).

#### 1985 recall of 1980 smoking habits

When asked in 1985 to recall 1980 smoking habits, about 8% of subjects disagreed with earlier statements as to whether or not they had been smoking manufactured cigarettes, or had been smoking any product. This disagreement was somewhat higher in men than in women.

Within men who reported smoking in 1980 on both occasions, over 31% disagreed about the types of product smoked. There was considerable discrepancy between the two sources of information

concerning number of cigarettes smoked and brand smoked but not regarding whether the brand was filter or plain.

Where errors or recall were made, there was a general tendency for these to be in the direction of current smoking habits. This was true for type of product smoked, number of cigarettes smoked (particularly among heavier smokers) and for brand smoked.

#### Memory of events prior to 1980

There was considerable discrepancy between answers to similar questions asked in both surveys concerning events prior to 1980 - age finished full-time education, age started smoking, year when gave up smoking, which products were smoked at the time of giving up and how many manufactured cigarettes were smoked at the time of giving up.

#### Changes in habits between 1980 and 1985

Between 1980 and 1985 more men and women gave up than took up smoking, and reduced than increased numbers of manufactured cigarettes.

### Digit preference

Smokers tend to preferentially report or recall numbers of manufactured cigarettes smoked as ending with a zero or to a lesser extent as ending with a 5. This was more marked when recalling number usually smoked than number smoked yesterday.

### Comparison with RP2 and RP2A

Due to differences in methods, the inconsistent groups we have discussed cannot be compared, but the 1952 and 1957 studies found similar levels of Type I current smokers as in the present study.

Findings on recall of smoking habits at the time of previous interview were similar regarding whether or not smoked, which products and how many cigarettes were smoked. Recall of which brand was smoked was much less accurate in the present study. The influence of present smoking habits on accuracy of recall was noted in both studies, but was less marked in the present study.

Findings on digit preference were similar in both studies.

INDEX - TEXT

1. Introduction	1- 2
2. Follow-up study methods	3- 5
3. Concordance between husband's and wife's smoking habits	6
4. Correlation between subject's smoking habits and other smoking in the household	7
5. Consistency of statements about age	8- 9

INDEX - TABLES

1. Concordance between husband's and wife's smoking habits.
2. Concordance between manufactured cigarette smoking habits of subject and other household members.
3. Comparison of ages as recorded in 1980 and 1985.
4. Comparison of ages recorded in 1980 and 1985 after exclusion of 15 reject follow-up questionnaires.
5. Difference between age as stated in 1980 and in 1985.
6. Consistency of 1980 and 1985 statements about smoking habits - any product.
7. Type I inconsistency of statements about smoking status.
8. Listing of data for subjects with Type I inconsistent status for smoking manufactured cigarettes.
9. Listing of data for subjects with Type I inconsistent status for smoking any product.
10. Duration of smoking among 1980 smokers.
11. Time of stopping smoking among 1980 ex-smokers.
12. Number of manufactured cigarettes smoked at time of giving up among 1980 ex-smokers.
13. Type II inconsistency of statements about smoking status - any product.
14. Listing of data for subjects with Type II inconsistent status for smoking any product.
15. Duration of smoking among 1985 smokers.
16. Time of stopping smoking among 1985 ex-smokers.
17. Number of manufactured cigarettes smoked at time of giving up among 1985 ex-smokers.
18. Listing of data for subjects with Type III inconsistent status.
19. Smoking by spouse and other members of household in 1980, by consistency of statements about own smoking habits.

20. Inconsistency rates among those whose spouse did or did not smoke, and among those where another household member did or did not smoke in 1980.
21. Smoking habits in 1980 - agreement between 1980 statements and 1985 recall statements.
22. Smoking habits in 1980 - agreement between 1980 statements and 1985 recall statements - broken down by age.
23. Type of product smoked in 1980 as stated in 1980 and as recalled in 1985.
24. Overall change in type of product smoked in 1980 as stated in 1980 and as recalled in 1985.
25. Accuracy of recall of 1980 smoking habits according to 1985 smoking habits.
26. Type of product smoked in 1980 - as stated in 1980 and as recalled in 1985, according to 1985 smoking products.
27. Accuracy of recall of type of product smoked according to 1985 smoking habits.
28. Number of manufactured cigarettes smoked in 1980 as stated in 1980 and as recalled in 1985.
29. Number of manufactured cigarettes smoked in 1980 as stated in 1980 and as recalled in 1985 - broken down by 1985 level of manufactured cigarette consumption.
30. Number of manufactured cigarettes smoked - Error in recall related to change in smoking between 1980 and 1985.
31. Errors of recall in brand smoked.
32. Age finished education - consistency of answers given in 1980 and 1985.
33. Age started smoking - consistency of answers given in 1980 and 1985.
34. Year gave up smoking - consistency of answers given in 1980 and 1985.
35. Which product smoked when gave up - consistency of answers given in 1980 and 1985.
36. Number of manufactured cigarettes smoked when gave up - consistency of answers given in 1980 and 1985.
37. Changes in smoking habits (any product) between 1980 and 1985 in relation to various other factors.

38. Changes in detailed smoking group between 1980 and 1985.
39. Change in number of manufactured cigarettes smoked between 1980 and 1985.
40. Changes in filter/plain smoking habits between 1980 and 1985.
41. Reporting of manufactured cigarettes smoked as round numbers.
42. Inconsistency in smoking habits (any product) related to inconsistency in age.
43. Combined Type I, II and III smoking habit inconsistency by between-survey age difference in age at finish of education.
44. Inconsistency on age of starting to smoke by between-survey age difference and between-survey age difference in age at finish of education.
45. Inconsistency on age of starting to smoke by between-survey age difference and between-survey difference in year stopped smoking.
46. Inconsistency on age of starting to smoke by between-survey age difference and between-survey difference in number of manufactured cigarettes smoked at time of giving up.
47. Discrepancies in recalling smoking at time of previous interview.
48. Informants who recalled, correctly or incorrectly, the type of product smoked at earlier interview.
49. % of subjects smoking various amounts of manufactured cigarettes - as stated at original interview and as recalled at follow-up interview.
50. % of subjects falling into same or different categories at two interviews when categorised by number of manufactured cigarettes smoked.
51. Recall of number of manufactured cigarettes smoked - correlation between memory error and change in amount smoked.
52. Recall of number of manufactured cigarettes smoked - comparison of correlation between current/recall and current/original.
53. % reporting manufactured cigarettes smoked as round numbers.
54. Summary of Type I, II and III inconsistencies (any product).

INDEX - APPENDICES

- A. Follow-up questionnaire used in 1985.
- B. Relevant part of original questionnaire used in 1980.
- C. Distribution of 1980 variables for all subjects.
- D. Distribution of 1980 and 1985 variables for subjects followed-up.
- E. Comparison of subjects selected and not selected.
- F. Brand smoked in 1980 as reported at the time and as recalled.

TEXT

1. Introduction

Most studies in recent years investigating the relationship between smoking and disease have been based on self-reported smoking habits. The accuracy of statements about smoking habits is clearly of crucial importance to the conclusions of such studies, but little detailed research has been done on this since TRC's Research Papers 2 and 2A some twenty years ago.

That study was based on subjects originally interviewed in 1948-50 in the Annual Consumer Survey (ACS). They were re-interviewed in 1952, 1957 and 1964 to investigate errors made in recalling smoking habits over different lengths of time. The study described here was carried out along similar lines, with subjects from the 1980 ACS re-interviewed in 1985, in order to bring the research up-to-date.

The need for a new study was prompted by various factors. One is the change during the intervening 20 years in attitudes to smoking. The increasing public awareness of smoking and health issues and the decreasing social acceptability of smoking may well prompt an increasing proportion of smokers to deny smoking, or cause those who have cut down to exaggerate past smoking.

Secondly, the accuracy of statements about smoking becomes even more important when studying the possible effects of passive smoking on health, since misclassification of active smokers as non-smokers can cause an appreciable bias.

Studies of the type considered here are concerned with consistency of repeated statements over time by the same individual and the reliability of recall of past events. In a separate study, currently ongoing, an objective measure (salivary cotinine) is being used to assess reliability of a single statement about current smoking habits.

## 2. Follow-up Study methods

The 1980 ACS interviewed 8,600 subjects age 16+ from 176 sampling points. The follow-up study was restricted to those aged 25-65 in 1980. Those aged under 25 were omitted on the grounds that they were less likely to have changed their smoking habits by that age, and also that a very low success rate would be expected in re-interviewing this age group, due to their mobility. Those aged over 65 were omitted to minimize problems including decreased survival and increased illness and loss of memory. The total sample eligible for re-interview was thus reduced to 5289, an average of 30 subjects at each sampling point. 80 sampling points were selected, preserving the regional balance of the original 176, and the interviewers were asked to locate (based on knowledge of name, initial, sex and address, but not age) and interview 7 subjects from each point, subject to quotas on sex and age (4 men and 3 women or 4 women and 3 men, not more than 1 subject aged 65-70), with the objective of obtaining at least 500 follow-up interviews. When identifying the subject, no reference was made to the fact that a previous interview had been carried out in 1980, in order to make the circumstances of interview in 1985 as similar as possible to the normal ACS interview situation, and not to alert subjects to the objective of the study.

The questionnaire used in the follow-up (Appendix A) was largely a repeat of the relevant parts of the ACS questionnaire

(Appendix B), covering general smoking status, details on manufactured cigarette smoking and various demographic details. Though the full ACS questionnaire asked a number of questions on smoking not asked in the follow-up, the questions asked on smoking on both occasions were asked first so answers should not be affected by the presence or absence of these additional questions on smoking. The ACS questionnaire in 1980 also had questions about smoking of manufactured cigarettes by other members of the household. The follow-up questionnaire did not ask questions regarding smoking by other members of the household, but added questions asking the subjects to recall their own smoking habits in 1980. These recall questions were asked after the standard ACS questions on smoking so as not to affect answers to the latter.

The data were received from Research Services on three tapes. TAPE1 contained 2 original cards for 2605 subjects in the districts not selected for follow-up. TAPE2 contained 2 original and 2 follow-up cards for the 555 persons re-interviewed. TAPE3 contained 2 original cards for 2129 persons in the districts selected, but who were not re-interviewed. On all three tapes, card 2 was omitted if the subject had never smoked manufactured cigarettes.

Two data files were set up for the analysis. ACS80.DAT contains the relevant data from the original study for all subjects, plus a variable indicating follow-up status derived

from the tape number. Appendix C gives details of the source of each variable from the cards, and gives the distribution of each variable by follow-up status.

FOLLOWUP.DAT contains data from both original and follow-up questionnaires for those people who were re-interviewed. Details are given in Appendix D. The distributions of variables based on the same question asked at different times are presented side by side.

3. Concordance between husband's and wife's smoking habits

Based on the total 1980 data for those who are married, a number of analyses were carried out relating the subject's own manufactured cigarette smoking habits (never, ex, 0-17, 18-22, 23+) to whether or not the spouse was reported by the subject to smoke manufactured cigarettes. As shown in Table 1, the percentage of subjects who have a spouse who smokes rises steadily with the subject's own manufactured cigarette smoking habits. After standardising for age, sex and social class, this trend is similar and highly significant ( $p < 0.001$ ) in both sexes individually, with, overall, current manufactured cigarette smokers some 2.7 times more likely than never smokers to have a spouse who smokes manufactured cigarettes. The trend is evident in all age and social class groups, but is rather more marked in the young than in the old and in ABC1 than in C2DE.

4. Correlation between subject's smoking habits and other smokers in the household.

As shown in Table 2, there is also a clear positive association between manufactured cigarette smoking with whether there is another smoker other than the spouse in the household, after adjusting for household size. Overall, 73% of never smokers and 74% of ex-smokers lived in a household with no other smoker, as compared with respectively 60%, 63% and 53% of current smokers of 0-17, 18-22 and 23+ manufactured cigarettes per day.

Thus, the study provided evidence that smokers were not only more likely to be married to smokers, but were also more likely to live in the same house as smokers other than the spouse.

5. Consistency of statements about age

As the original interviews were carried out towards the end of 1980, the subjects would have been either 4 or 5 years older in the 1985 survey. Some minor inaccuracies or roundings might have been expected, particularly if age was estimated by the interviewer, but it was found that there were a large number of discrepancies, some of them fairly gross.

In Table 3, the subjects are classified into 5-year age groups, and the figures ringed indicate those subjects where the discrepancy was by more than one age group.

The size of some of these discrepancies led to the suspicion that the wrong person had been interviewed in the follow-up - probably a relative with the same initial living in the same household. A detailed examination of the questionnaires was carried out for the 165 subjects who did not have the expected 4/5-year age difference. For 150 subjects this resulted in a positive identification that the follow-up interview had been conducted with the correct person. In 6 cases the follow-up was found to be with the wrong person, while a further 9 cases were uncertain. It was decided to reject all these 15 cases from the follow-up study.

Table 4 shows a revised comparison of age groups for the remaining 540 subjects.

Table 5 is based on the difference between exact ages stated in 1980 and 1985. The discrepancies may be explained as:

- a) age estimated at either interview by the interviewer.
- b) respondents not remembering their exact age.
- c) respondents lying about their age.
- d) interviewers changing ages to fit survey quotas.

The age as stated in 1980 is used in all subsequent analyses.

6. Representativeness of follow-up sample

As the response rates obtained from different demographic groups would be expected to vary under the selection procedure, it is necessary to assess the representativeness of the follow-up sample.

The 1980 answers for a number of factors were compared between those re-interviewed and those not re-interviewed (or rejected). These comparisons are given in Appendix E. A number of significant differences were seen, and the effect on the follow-up sample can be summarised as follows:

A male subject was more likely to have been re-interviewed if

- he
- was age 35 or over (in 1980).
  - was in social class C2DE.
  - finished full-time education age 15 or under
  - lived in a large household.
  - was originally interviewed at home.
  - was originally interviewed on a Saturday.
  - was an ex-smoker or never smoker of cigars (as opposed to current or occasional).

A female subject was more likely to have been re-interviewed if

- she - was married.
- was not working, or working part-time.
- lived in a large household.
- was originally interviewed at home
- was a current hand-rolled smoker.

No differences were seen in respect of sex, length of original interview, manufactured cigarette smoking habits, or pipe smoking habits.

The differences found seem to follow a plausible pattern, with the interviewer less likely to get hold of young, mobile, at work people.

In order to check that these differences were not due to the 80 sampling points selected being unrepresentative of the total, some further comparisons were made between all subjects in selected areas and those in non-selected areas. These comparisons showed virtually identical distributions as regards sex, age, social class and manufactured cigarette smoking habits.

7. Main analysis - introduction

The main analysis of the study was seen as providing answers to the following 3 questions:

- (a) Were answers about general smoker status in 1985 consistent with answers to similar questions in 1980?
- (b) When specifically asked in 1985 to recall details of 1980 smoking habits, how good was memory compared with answers given at the time, and was memory affected by current smoking habits?
- (c) How did memory of events prior to 1980 compare in the 2 surveys?

A fourth question was also looked at, namely:

- (d) How had habits changed between 1980 and 1985 and to which factors did these changes relate?

8. Consistency of statements about smoking status

If one defines the subjects according to both the 1980 and 1985 statements separately as "current", "ex" or "never" smokers of any product, and if the 1985 subjects are further divided by whether they started and/or stopped smoking before or after 1980, then it is clear that certain combinations of replies are inconsistent.

It was found that no subject claimed to have started smoking after 1980, and a further check ascertained that no combination of starting/stopping dates was inconsistent. This somewhat simplified the various possibilities which are summarized in Table 6. Certain groups are highlighted and are dealt with in detail in the following sections, viz.

- I: subjects who in 1980 stated they smoked or had smoked in the past but who in 1985 claimed never to have smoked;
- II: subjects who in 1980 said they had never smoked, but who in 1985 claimed to have started smoking by 1980;
- III: current smokers in 1980 who claimed in 1985 to have given up before 1980.

A problem in these definitions of type I and type III inconsistency arises from the wording of the questions about manufactured cigarettes, handrolled cigarettes and pipes. The basis of current smoker status is the simple question "Do you

smoke ...?". However, ex-smoker status is based on the more strictly defined question "Have you ever smoked at least one ... a day for as long as a year?", and the time of giving up relates to giving up smoking at this level. Hence, a subject who was smoking only occasionally in 1980 and who had given up by 1985 would be classified as a current smoker in 1980 but as a never smoker in 1985, thus erroneously appearing as type I inconsistent. Similarly, a regular smoker who had reduced his level of smoking below the defined level by 1980 and given up by 1985 would erroneously appear as a type III inconsistent. This possible explanation for some of the inconsistencies is investigated in the relevant sections. (The problem does not arise for type II inconsistency, nor for smoking of cigars.)

It can be noted that the information on age of starting to smoke and year of giving up, on which Table 6 is based, relate to overall smoking and not to specific products. However, as these items are not used in identifying type I inconsistent subjects, it is additionally possible to study type I inconsistency for individual products.

When considering inconsistency in overall smoking, this ignores possible inconsistent changes of product (e.g. pipe smoker in 1980, only ever manufactured cigarettes in 1985).

8.1 Type I inconsistency

Table 7 gives the number claiming to be "never" smokers in 1985 and shows how many previously claimed to be current or ex-smokers. Figures are given for each product separately and for smoking any product.

This shows that those who reported never having smoked by 1985 contain a substantial proportion who had apparently smoked in the past. This proportion is particularly high for men, being 17.9% for manufactured cigarettes and 14.8% for any product; in the 55-65 age group, the proportion reached 30% and 50% respectively, although these figures are based on the relatively small number of never smokers in this age group.

The individual data for manufactured cigarettes and for any product were examined (Tables 8 and 9) to see if occasional smoking provided a possible explanation for any of the inconsistencies.

The possibilities to consider for manufactured cigarette smoking, (i.e. those involving current smoking) were:

Serial No.	No.cigs.
11451	20
12290	12
12525	6
21855	1
23237	1

There were no additional possibilities for smoking any product. The first two of these were also the only two subjects to show inconsistency within the 1985 questionnaire, by claiming never to have smoked but recalling smoking 20 and 10 cigarettes a day respectively in 1980. These agree well with their 1980 statements, and suggest that the 1985 statements on smoking status are false, possibly due to the subject not understanding the questions.

The third (serial no.12525), smoking only 6 manufactured cigarettes "yesterday" in 1980 and being a continuing handrolled cigarette smoker, may fit into the "loophole" of an occasional smoker, as most likely do the final two subjects (serial nos. 21855 and 23237), both smoking 1 cigarette yesterday.

If these 3 were treated as never regular smokers, then the adjusted % inconsistencies shown in the final 2 columns of Table 7 are obtained. The overall pattern would be little affected. Thus, for men the Type I inconsistency rate for manufactured cigarette smoking would fall from 17.9% to 16.4% after adjustment, while that for women would fall from 5.3% to 3.5%.

It was not possible to assess whether the other current inconsistent smokers (7 handrolled, 3 pipe) included occasional smokers, since there were no questions about the quantity smoked of these products.

A number of factors were studied to see if they were associated with the level of inconsistency.

One possible cause of inconsistent statements is a tendency to ignore smoking of short duration. To investigate this, the number of years smoked (based on age started and year stopped if appropriate) was compared between the 1980 smokers (current or ex) who later claimed, inconsistently, to be never smokers and the 1980 smokers who continued to claim to be smokers by 1985. This analysis is given in Table 10. As can be seen, the level of inconsistency decreased with the number of years smoked (trend  $p < 0.01$ ).

Among ex-smokers, comparisons could also be made of how long ago smoking stopped, and the number of manufactured cigarettes smoked at that time (Tables 11 and 12). Here, the comparison is between the 1980 ex-smokers who later claimed to be never smokers, with the 1980 ex-smokers who continued to claim to be ex-smokers in 1985 (excluding those few who in 1985 stated giving up since 1980, since they may indeed have re-started and stopped in the intervening 5 years). As can be seen, the proportion who in 1980 reported giving up before 1970 was higher in the inconsistent group (66.7%) than in the consistent group (31.7%). However, sample sizes were small and the difference was only

significant at the 90% confidence level. There is also a very marked trend towards a lower number smoked by the inconsistent group. Despite the small sample size in this group, this trend was quite highly significant ( $p < 0.01$ ).

## 8.2 Type II inconsistency

Looking at the same problem but with the times reversed, we now turn to Type II inconsistency, i.e. study of those who stated that they had never smoked in 1980, but who were current or ex-smokers in 1985.

There were 2 such subjects (aged 63 and 45) for whom age of starting to smoke was missing. As there were no subjects at all claiming to have started smoking after 1980, it seems reasonable to assume that these 2 also started before 1980.

As shown in Table 13, those claiming never to have smoked by 1980 contain a considerable number who later stated that they had smoked by that time, namely 22.0% of males and 7.8% of females. As with the previous type of inconsistency, the highest proportion was among males aged 55-65 with 55.6% (5 out of 9) inconsistencies. A listing of subjects with Type II inconsistency is shown in Table 14.

As for Type I inconsistency, it is of interest to compare duration of smoking, time of stopping smoking and number of cigarettes smoked at time of giving up for Type II inconsistent and comparable consistent smokers. Here, the subjects to be studied are those who in 1985 stated they were smokers who had started before 1980, and the comparison is between those who were never smokers (inconsistent) and those who were current or ex-smokers (consistent) in 1980. Results are given in Tables 15,16 and 17. It can be seen that there is a tendency for the Type II inconsistent subjects to have reported smoking for fewer years. 33.3% (7/21) of the inconsistent group had smoked for 10 years or less compared with 4.4% (14/318) of the consistent group (trend  $p < 0.05$ ). They also reported stopping smoking earlier (trend  $p < 0.05$ ), and to have smoked fewer manufactured cigarettes at the time of giving up (trend  $p < 0.01$ ).

### 8.3 Type III inconsistency

Among the 53 subjects who said they were current smokers in 1980 but ex-smokers in 1985, 2 subjects (3.8%) claimed to have given up before 1980, and their details are given in Table 18.

The first (serial 10201) claimed on both occasions to be an ex-smoker of 40 manufactured cigarettes per day, but his 1980 current cigar smoking was denied in 1985, despite the stricter form of question being used on both questionnaires for cigars. Hence the 1985 claim to have given up smoking in 1971 presumably relates to manufactured cigarettes only.

The second (serial 22819) stated having given up in 1979 and may possibly have been an occasional smoker in 1980. However it seems more likely that this inconsistency can be attributed to a slight error in recalling the year of giving up. (Recall of year of giving up is also considered in section 10.)

Two further subjects (serial 22380, 23315) are also listed. These did not state when they gave up smoking, so their consistency cannot be assessed. (They are treated as consistent in subsequent analyses.)

#### 8.4 Inconsistency of smoking habits related to other smokers in the household

Having identified three groups of subjects with inconsistent statements on smoking habit, it is of interest to investigate the proportion who are married to smokers, or who live in a household

with other smokers, compared with those giving consistent statements. Table 19 gives the proportion in each group who stated in 1980 that they were married to a smoker or that another household member smoked. It can be seen, in line with the findings of Section 3, that more consistent smokers (45.4%) than consistent never smokers (29.2%) were married to a smoker ( $p < .005$ ). The proportion for type I inconsistent subjects (38.5%) was almost the same as for consistent smokers, but for type II (11.1%) was significantly lower. Indeed, this is much lower (although not significantly) than the consistent never smokers. Bearing in mind that it was in 1980 that the type II subjects denied smoking, this is consistent with 2 hypotheses - (a) that a subject who denies his own smoking is likely to deny his spouse's smoking at the same time or (b) that a smoker married to a non-smoker is likely to deny his own smoking. Similarly for the proportions in each group where there was another smoker in the household other than the spouse, the differences were generally in the same direction, but none were significant.

In Table 20 the inconsistency rates for the three types of inconsistency among comparable consistent subjects are shown, broken down by whether the spouse or another household member smokes. It can be seen that the Type I inconsistency rate is higher (although not significantly) among those who claimed that their spouse smoked than among those who claimed that their spouse did not smoke, whereas the difference in the Type II inconsistency rates is in the opposite direction.

9. Recall of 1980 smoking habits in 1985

In the 1985 interview, questions were asked regarding whether in 1980 the subject had smoked manufactured cigarettes, had smoked handrolled cigarettes, had smoked a pipe, had smoked as much as one cigar a week in 1980 and, for those who said they smoked manufactured cigarettes, the number they had smoked on average and the brand smoked most often. These answers can be compared with answers to similar questions asked in 1980, although the questions about manufactured cigarettes are not exactly comparable - the original questions asked how many cigarettes were smoked yesterday and what was the last brand bought.

9.1 Recall of types of product smoked

Table 21 compares 1985 memory with actual 1980 statements for each smoking product and for a summary of overall smoking. For manufactured cigarette smoking and for overall smoking of any product, there was about an 8% discrepancy rate, with most of the discrepancies being cases where the subject had not stated smoking in 1980 but recalled smoking when asked in 1985. That is, more subjects overstated than understated their past smoking habits. The discrepancy rate was slightly higher for men than for women, but was not obviously age-related (as illustrated in Table 22, which shows results for manufactured cigarettes broken down by age).

For men, the percentages with discrepant answers were 8.8 for handrolled, 6.4 for pipes, 10.8 for cigars. For handrolled and cigars, the rate of discrepancy was similar in both directions.

Within the 127 men who stated both in 1985 and in 1980 that they smoked in 1980, there was disagreement in 40 cases (31.5%) about the type of product smoked, when subjects were classified according to manufactured only, handrolled only, or both, pipe only, cigars only, or both, or cigarettes and pipe/cigar (see Table 23). In all but 2 of these cases, the discrepancy was between one product and mixed including that product, with the rate similar in both directions.

However, if these answers were used to assess the products smoked overall, rather than on an individual basis, very little discrepancy would be seen (Table 24).

In Research Paper 2A, it was found that subjects tended to make errors of recall more in the direction of their own current habits than in the reverse direction. For a simple yes/no breakdown of smoking for a particular type of product, this finding can be tested by comparing, given the 1980 statement, the proportion who recall correctly among those who have not changed their habits with the corresponding proportion among those who have changed their habits. Results for individual types of

product and for any product are given in Table 25. As can be seen our results fit in well with the conclusions of RP2A, in all 10 comparisons made, the percentage who recalled incorrectly being higher, usually very markedly, where 1980 and 1985 habits differed than where they were the same.

Recall of all types of products smoked, as classified above, is examined further in Tables 26 and 27 broken down by 1985 smoking habits. Although the numbers in some categories are small, it can be seen that recall of types of product was most accurate among those still smoking the same product(s) (91.7%). Those who had given up smoking by 1985 recalled more accurately (66.7%) than those who had changed product(s) (50.0%). Among those who had changed products and who recalled inaccurately, 60% stated the same products as their current smoking, i.e. they thought they had not changed products.

#### 9.2 Recall of number of manufactured cigarettes smoked.

Within those subjects who reported on both occasions that they had smoked manufactured cigarettes in 1980, there was considerable discrepancy as regards the number reported to be smoked (Table 28). Even when number smoked was divided into only 3 categories (-17, 18-22, 23+) as many as 86 out of 219 (39%) of manufactured cigarette smokers recalled a different category from that originally reported.

The question as to whether recall of past smoking was based more on current smoking than on actual past smoking, was examined in 3 ways.

Firstly, the correspondence between the two statements about 1980 smoking was examined separately for each level of 1985 smoking. This is shown in Table 29, which is based on all subjects who smoked manufactured cigarettes either in 1980 or 1985. If the recall statement reflected the actual 1980 statement, then the figures would appear grouped down the diagonal of each sub-table; on the other hand, if recall was based on current (1985) smoking, then the figures would congregate around the row corresponding to the 1985 level. In fact, the figures seen are:

1985 statement	Recall statement corresponds with 1980 statement (diagonal)		Recall statement corresponds with 1985 statement (row)		Total number of subjects
	N	%	N	%	
0- 7	49	59.0	25	30.1	83
8-17	38	53.5	32	45.1	71
18-22	26	45.6	40	70.2	57
23-32	7	31.8	11	50.0	22
33+	4	50.0	7	87.5	8

This suggests that accuracy of recall was greater among those smoking small amounts in 1985, and that the tendency to base recall upon current smoking is greater among heavier smokers.

The second approach was to consider the change in smoking level from 1980 to 1985. Assuming for the moment that the statements made about current smoking at both times were accurate, a subject whose smoking had not changed had an easier task recalling past smoking; also, subjects who had reduced their smoking level might be expected to understate their past smoking. Table 30 gives details, by amount changed between 1980 and 1985, of the proportion who, from their recall in 1985, understated or overstated 1980 habits, or were approximately correct.

This confirms that those who had not changed were indeed most likely, with 67%, to recall accurately. Of those who had reduced by a small amount, 39% recalled accurately, while of those with larger reductions or any increase, only 20-30% recalled accurately. Among those who did not recall accurately, those whose smoking had reduced were somewhat more likely to understate than overstate (62.2% against 37.8%), whereas those whose smoking had increased tended overwhelmingly to overstate (10.5% against 89.6%).

Table 30 also cross-tabulates recalled change in smoking level against actual change. It can be seen that, of 53 subjects who had actually increased their number smoked, as many as 29 (54.7%) recalled no change, basing their recalled answer on current levels. This tendency was less marked in those who had actually decreased their number smoked (33 out of 131 = 25.2%). The number recalling no change when one had actually occurred (62) considerably exceeded the number recalling a change when none had occurred (21).

Finally, the possibility that 1980 recall was affected by 1985 smoking habits was examined by testing whether 1985 recall of manufactured cigarette smoking habits correlated more closely with 1985 statements of habits than with 1980 statements. This was done for all subjects who had smoked manufactured cigarettes in either 1980 or 1985, separately for those whose smoking had increased or decreased.

Among those who had increased their smoking level, the correlation between recall and 1985 smoking (.79) was stronger than the correlation between recall and 1980 smoking (.63). However, among those who had decreased their smoking, the correlation between recall and 1985 (.13) was considerably weaker than between recall and 1980 (.52).

### 9.3 Recall of brand smoked

For those who reported on both occasions smoking manufactured cigarettes in 1980, the brand reported in 1980 to have been last bought was compared with the brand reported in 1985 to have been smoked most often in 1980. This was restricted to those 191 smokers of manufactured cigarettes who gave a specific brand in 1980, who recalled a specific 1980 brand in 1985, and who in 1985 stated they either smoked a specific brand or were a non-smoker. The rate of agreement was fairly low (45.0%). When the brands were used to determine if the subject smoked plain or filter, there was much better agreement, with only 1 discrepancy out of the 16 who originally stated they smoked plain, and 2 discrepancies out of 175 filter smokers.

7 subjects recalled a brand that was not available in 1980.

When the brands were used additionally to determine cigarette size, there was a 67.0% agreement rate, with the discrepancy rate the same in both directions, 30 of the 173 consistent filter smokers recalling a larger size than reported originally and 30 recalling a smaller size (Table 31).

Appendix F lists details of the relevant brands smoked. Table 31 also contains a summary breakdown of the findings. Not surprisingly, recall of the 1980 brand was most often correct when the subject continued to smoke the same brand in 1985 as in 1980 (41/52 = 78.9%). Recall of the 1980 brand was more often correct among those who were not smoking manufactured cigarettes in 1985 (23/48 = 47.9%) than among those who continued to smoke manufactured cigarettes but had changed their brand (22/91 = 24.2%). Among the 69 incorrect recalls of 1980 brand in the latter group, 20 of them were cases where the brand recalled was actually that smoked in 1985. This proportion (29.0%) is much greater than expected by chance (2.2%) and is further evidence that, when recalling, smokers tend to err in the direction of their current habits.

10. Memory of events prior to 1980

Similar questions were asked in both surveys about age finished full-time education, age started smoking, year when gave up smoking, which products smoked at the time of giving up smoking and the number of manufactured cigarettes smoked at the time of giving up smoking. The answers on the 2 occasions were compared respectively for the 5 questions in Tables 32-36.

Most subjects might be expected to have a fixed idea as to the age at which they finished their full-time education. However, when classified as up to 15,16,17,18,19-23 or 24/not finished, there was a discrepancy rate of 19.4%, or 3.4% by more than 1 category (Table 32).

When comparing age of starting to smoke among those who claimed at both times to have ever smoked, the subjects were classified as starting under 12, 12-13, 14-15, 16-17, 18-19, 20-24 or 25+. The rate of discrepancy by more than one category was 10.2% for men and 6.3% for women. The majority of these men and all of these women claimed younger starting in 1980 than they did in 1985. All those who claimed to have started older (by more than one category) in 1980 than in 1985 were aged 45 or over (Table 33).

For 72 subjects who claimed on both occasions to be ex-smokers, the year of giving up smoking was compared, classified as up to 1940, 1941-50, 1951-60, 1961-65, 1966-70, 1971-75, 1976-80 and 1981-85. 9 subjects stated in 1985 that they had given up since 1980, and they may indeed have restarted and stopped in this period. However, as 8 of them stated in 1980 to have given up in 1976-80, it seems likely that some at least of these are discrepancies in memory. Of the remaining 63 subjects, there were 39.7% discrepancies, or 3.2% (2 subjects) by more than one category (Table 34).

Which products were smoked at the time of giving up were compared for 38 men, classified as manufactured or handrolled cigarettes, or both, pipe, cigars, or both, cigarettes and pipe and/or cigars (Table 35). 19 men agreed smoking only manufactured cigarettes, and a further 4 agreements left 15 (39.5%) discrepancies. All but 2 of these were between smokers of cigarettes only and smokers of multiple products including cigarettes. Table 35 also shows that of 25 women, there was only 1 discrepancy, a woman who reported smoking manufactured cigarettes only in 1980 but manufactured plus handrolled in 1985.

For those subjects who in 1980 claimed to be ex-smokers of manufactured cigarettes and who in 1985 claimed also to be ex-smokers, having given up before 1980, the number of

manufactured cigarettes smoked, grouped into 7 categories (1-7, 8-12, 13-17, 18-22, 23-27, 28-32 and 33+) was compared (Table 36). Of the 71 subjects, 40 (56.3%) reported the same category, a further 18 (25.4%) reported only one category different, while 13 (18.3%) reported a difference of more than one category.

11. Change in smoking habits between 1980 and 1985

Data on smoking habits measured at two time points, apart from being used to detect inconsistencies in statements made, can also be used to determine what changes have occurred and how they relate to other factors. This latter use, though not strictly related to the objectives of the study, was investigated by carrying out analyses of changes in smoking habits between 1980 and 1985 after excluding those subjects that gave type I, II or III inconsistent answers. As noted in Section 8, no subjects claimed to have started smoking since 1980.

Table 37 gives, broken down by age, sex, change in social class and change in employment status, the proportions of subjects who had changed from being an ex-smoker in 1980 to being a smoker in 1985 and vice versa. Overall, the fact that 53 subjects had become ex-smokers as against only 11 subjects who had become smokers, confirms the general downward trend in percentages of smokers evident from sales statistics and annual surveys. This general trend was evident in all subgroups with adequate numbers.

The tendency to give up smoking was slightly but not significantly more marked in men than in women, but was not obviously age-related. In men, there was no relation between

change in social class and giving up smoking, but in women there was a tendency for those who had increased social class to be more likely to give up ( $p < 0.05$ ). No significant relationship of change in smoking habits to change in employment status was seen, though it was interesting that in men, the highest proportion of those giving up smoking was in the group who had become unemployed.

The tendency to restart smoking could only show up gross differences by the factors studied, due to the small numbers. The only significant difference found was a tendency for younger men to take up smoking more than older men ( $p < 0.05$ ).

Table 38 compares products smoked in 1980 and 1985. In both sexes, marked reductions have occurred in the number who smoked manufactured cigarettes only. No discernible changes have occurred in respect of other products.

Table 39 compares numbers of manufactured cigarettes smoked in 1980 and 1985. In men, 17 (23.6%) reported smoking in the same group, 34 (47.2%) reported a decrease and 21 (29.2%) an increase. In women, 38 (38%) reported smoking in the same group, 43 (43%) reported a decrease and 19 (19%) an increase.

As shown in Table 40, only 10 plain smokers were seen in 1980, 9 of them male. By 1985, 3 of these had switched to filter, with none switching to plain.

12. Digit preference

One indication of possible inaccuracy about the recording of number of manufactured cigarettes smoked is the tendency to record numbers divisible by 10 or by 5. Although there is no doubt some smokers do in fact buy one (or two) packets a day, this tendency, as illustrated in Table 41, is so strong as to suggest most smokers mentally round the numbers they report smoking. Thus, in 1980, over half of men (57.7%) and almost half of women (44.4%) who reported smoking manufactured cigarettes, stated a number ending in a zero, with about 40% of the remainder in both sexes stating a number ending in a five. In 1985, the tendency to round was slightly less marked than in 1980, 48.7% of men and 34.6% of women stating a number ending in a zero, with about 30% of the remainder in both sexes stating a number ending in a five. The tendency to round was greatest of all for 1985 recall of 1980 smoking habits, with 68.1% of men and 57.9% of women stating a number ending in a zero and some 60% of the remainder in both sexes stating a number ending in a five. Since recall related to average number smoked in 1980, whereas current smoking related to yesterday (or Saturday on half the interviews carried out on Monday), it was not surprising that the tendency to round was greatest for the recall situation.

13. Inconsistency of age related to inconsistency of smoking habits

As noted in Section 6, a number of inconsistencies were seen in the ages given at the two surveys. Although it is possible that some of these inconsistencies may be due to the interviewer falsifying the age to fit the survey quota, the remainder can be attributed to the subject giving an unreliable response, or declining to respond at all. It is of interest to examine if inconsistency of age was related to the inconsistencies we have discussed in statements about smoking habits.

Accordingly, comparisons of inconsistency rates were made between those 390 subjects who had a between-survey age difference of 4 to 5 years, those 106 subjects who had a between-survey age difference of 1 to 9 years (other than 4 to 5 years) and those 44 subjects who had a between-survey age difference other than 1 to 9 years. Results are given in Table 42, which classifies subjects into 7 categories; Type I, II or III inconsistent, consistent never smoker, consistent smoker/ex-smoker with ages of starting consistent, 1 or 2 years different, or 3 or more years different.

The proportion of the total population with Type I, II or III consistency can be seen from Table 42 to be lower in those with the expected between-survey age difference of 4 to 5 years ( $20/390=5.1\%$ ) than in those with other age-differences

(14/106=13.2% for other 1 to 9 year differences; 4/44=9.1% for other differences). The last two percentages did not differ significantly, but the first was significantly ( $p<0.01$ ) lower than the other two combined.

The remainder of the population can be divided into those who consistently stated they had never smoked and those who consistently stated they smoked or had smoked in the past. Among those who were consistent smokers/ex-smokers one can compare the percentage who gave an age of starting to smoke on the two occasions which differed by 3 years or more (or who on one or both of the occasions failed to remember the age of starting to smoke at all). Again this proportion was less in those with the expected between-survey age difference of 4 to 5 years (62/256=24.2%) than in those with other age-differences (23/67=34.3% for other 1 to 9 year differences; 7/27=25.9% for other differences). For this indicator of inconsistency, the first percentage did not differ significantly ( $0.05<p<0.1$ ) from the other two combined.

Some attempt was made to gain further insight into this question by relating inconsistency on smoking habits and on age to other types of inconsistency. Tables 43 and 44 give information relating to consistency of statements about age of finish of education. It can be seen that, given between-survey age difference, neither the proportion of the total population with type I, II or III inconsistency (Table 43) nor the

proportion of consistent smokers/ex-smokers with inconsistent ages of starting to smoke (Table 44) related to whether the two statements made about age of finish of education were, or were not, inconsistent.

Tables 45 and 46 show that, among consistent ex-smokers, the proportion with inconsistent ages of starting to smoke (given between-survey age difference) did not obviously relate to whether or not statements about the year of stopping smoking or the number of cigarettes smoked at the time of stopping were consistent. However, numbers in these tables are rather small.

14. Comparison with findings of Research Papers 2 and 2A

Although the present study was conducted generally along similar lines to the original study, a number of differences make detailed comparisons difficult:

- (a) Research Papers 2 and 2A (RP2, RP2A) did not give the questionnaires used.
- (b) No details were described of the procedure for following-up people.
- (c) No assessment was made of consistency of answers about age or any other non-smoking factor.
- (d) At the original interview, the subjects appear only to have been asked about current smoking, while at the follow-up interview they were first asked if they currently smoked, then if they smoked at the time of the previous interview and, only if they said no to both questions were they asked if they had ever smoked regularly. Hence, it is not possible to identify inconsistent groups as in the present study. However, they did note that in the 1952 Memory Enquiry (of 982 men and 306 women), there were no men but 6 women who were current smokers at the original interview but claimed never to have smoked at the follow-up interview (0.5% overall).

Similarly, in the 1957 Memory Enquiry, there were 6 such men (of 662 previously interviewed = 0.9%). These are equivalent to the 1980 current smokers among our Type I inconsistent group (0.7% overall, or 0.4% after adjustment for occasional smokers).

- (e) Most attention was given in RP2 and RP2A to reliability of recall of smoking at the time of the previous interview. A number of comparisons can be made (section 14.1-14.4), but in the present study all the original interviews were conducted in the same year, hence we are not able to assess reliability over varying periods of time, nor to study a third interview with the subject, as in the 1957 Memory Study.
- (f) Changes in the importance of some types of smoking (e.g. importance of handrolling in the 1940s, increased consumption of cigars, which were not studied at all in RP2) have made some comparisons difficult.
- (g) In RP2 and RP2A quantities of handrolled and pipe tobacco smoked have been expressed as manufactured cigarette equivalents and used to calculate total tobacco consumption levels, whereas they were not measured in the present study.

#### 14.1 Recall of type of product smoked

The two studies found similar levels of discrepancy in recalling smoking, or smoking a particular product; also that more subjects who had originally not smoked (or not smoked a particular product) incorrectly recalled having smoked, than subjects who had smoked originally but recalled incorrectly having been a non-smoker (Table 47).

In Table 23 we found that among subjects who correctly recalled being smokers 73.2 % recalled all types of products correctly (after grouping smokers of both cigarettes and pipe/cigar). This compares with 82.1% of subjects reinterviewed in 1952 (RP2, Table 10A, cigars not considered).

Both studies found that current smoking influenced accuracy of recall of which products were smoked. However, this tendency appears less marked in the present study (Table 48).

#### 14.2 Recall of amount smoked

Both studies found considerable discrepancies in recall of amount smoked (Tables 49 and 50) and, as already discussed in section 9.2, that recall of amount smoked was influenced by current smoking levels (Tables 51 and 52). However, the

possibility that this tendency was stronger in heavier smokers, as in the present study, cannot be assessed from RP2.

#### 14.3 Recall of brand smoked

RP2 found a high correct recall rate (77.8%)\* in 1957 of the brand smoked in 1955/6, and that most of the incorrect recalls (presumably among subjects still smoking) were the same as the current brand (78.0%). This compares with 45.0% and 25.0% respectively (both sexes, after exclusion of unknown or unspecific brands) in the present study, and is presumably due to the smaller number of brands then available.

#### 14.4 Digit preference

Both studies observed the tendency for subjects to state cigarette consumption in terms of round figures (Table 53).

\* From Table 9B - N man cig smokers who in 1957 correctly recalled having smoked in 1955 or 1956 =  $106+125-5-1=225$ .

From Tables 19A and 19B, N incorrectly recalling brand =  $27+23=50$ .

15. Discussion

In most epidemiological studies of smoking and health, subjects are classified on a single occasion into those who have never smoked, those who have smoked in the past and those who currently smoke, with current smokers broken down by quantity smoked. It is clear that errors in classification will tend to bias the true relationship between smoking and the disease in question. If risk of the disease is greater in smokers than in non-smokers, the observed relationship with active smoking will tend to be less than actually exists when misclassification of smoking habits occurs. However, if the smoking habits of spouses are correlated, misclassification may tend to create an apparent positive effect of spouse's smoking on the risk of the disease in non-smokers when no true effect of passive smoking exists.

When a person claims never to have smoked, he may in fact be a current or an ex-smoker. The importance of an erroneous claim in assessing the relationship between active or passive smoking and a disease will tend to be greater for current than ex-smokers and for heavy than light smokers. That someone ignores having smoked 2 cigarettes a day 30 years ago may matter little, but denial of current smoking of 40 a day may cause severe bias.

Elsewhere, using salivary cotinine measurements, an attempt is being made to detect the proportion of people who claim to be non-smokers but who in fact currently smoke. One major objective of the current study is to gain some insight into the additional proportion who claim never to have smoked, but who have smoked in the past, by comparing statements made at different points in time. It is realised, of course, that this will still not determine the full extent of false claims about never having smoked, as there may well be some subjects who in fact gave up some years ago but who denied ever having smoked at each interview.

Table 54 summarises the cases observed of the 3 types of inconsistency we have defined, regarding smoking of any product:

- Type I : never smoked in 1985, current or ex-smoker in 1980.
- Type II : never smoked in 1980, current or ex-smoker in 1985 having started before 1980.
- Type III : current smoker in 1980, ex-smoker in 1985 having given up before 1980.

These involve 38 subjects out of the 540 studied (7.0%). As we have demonstrated in section 8, and is clear from Table 54 anyway, the great majority of Type I and II inconsistencies relate to cases where on one occasion the subject reported having smoked in the past and on the other having never smoked at all

(29/36 = 80.6%). Also, the quantity reported to have been smoked (when owned up to) was often quite low. Even so, of the total of 36 type I and II discrepancies, there were 18 where 10 or more cigarettes a day was reported on one occasion. If one arbitrarily defines this as a "major inconsistency", this gives the result:

Type I "major" : 8 out of 166 1985 never smokers = 4.8%

Type II "major" : 10 out of 174 1980 never smokers = 5.7%

Of the 18 "major inconsistencies", 1 relates to the subject reporting being a current smoker on one occasion, 17 to subjects reporting being ex-smokers.

In summary, we have observed that misclassification of smoking habits occurs and also that there is a marked positive correlation between spouse's smoking habits. The extent to which a bias resulting from a combination of these factors may explain the observed passive smoking/lung cancer association will be discussed at a later stage when the additional evidence from the salivary cotinine study becomes available.

TABLE 1

Concordance between husband's and wife's smoking habits

Percentage (base) whose spouse smokes by subject's own  
manufactured cigarette smoking habits and by sex, age or social class

	Subject's own man. cig. smoking habits				
	Never	Ex	0-17/day	18-22/day	23+/day
All subjects	27.2(1587)	30.9(922)	47.5(775)	49.8(522)	56.4(479)
Male	22.5(685)	27.8(587)	38.2(296)	45.7(276)	53.4(324)
Female	30.8(902)	36.4(355)	53.2(479)	54.5(246)	62.6(155)
Age 25-34	25.6(480)	29.7(185)	54.1(220)	58.9(141)	60.8(130)
35-44	27.7(476)	32.5(265)	47.8(226)	54.6(152)	63.3(158)
45-54	28.8(309)	28.9(187)	42.6(148)	44.9(127)	53.8(104)
55-65	27.3(322)	31.6(285)	43.1(181)	36.3(102)	40.2(87)
Social class ABC1	20.7(701)	25.1(415)	44.3(309)	45.3(159)	56.3(160)

Key : N = non-smoker, C = current smoker, Ex = ex-smoker  
 MC = manufactured cigarettes, HR = handrolled, CGR = cigar

TABLE 19

Smoking by spouse in 1980, by consistency of statements  
about own smoking habits

---

A. Married subjects

	1 % (base ) where spouse smokes	2 % (base ) with smoker other than spouse
Type I inconsistent	38.5 (13)	20.0 (5)
Type II inconsistent	11.1 (18)	0.0 (5)
Type III inconsistent	50.0 (2)	100.0 (1)
Consistent never smokers	29.2 (137)	28.9 (45)
Consistent smokers	45.4 (295)	32.7 (107)

B. Unmarried subjects

	3 % (base ) with other smoker
Type I inconsistent	- (0)
Type II inconsistent	0.0 (2)
Type III inconsistent	- (0)
Consistent never smokers	44.4 (9)
Consistent smokers	52.2 (23)

1. Married subjects.
2. Married subjects with adults in household apart from subject and spouse, but omitting any subjects claiming more smokers than adults in household.
3. Unmarried subjects with adults in household apart from subject, but omitting any subjects claiming more smokers than adults in household.

TABLE 20

Inconsistency rates among those whose spouse did or did not smoke, and among those where another household member did or did not smoke in 1980

A1. Married subjects

	Spouse smoked man.cigs in 1980	Total subjects	N with inconsistency	% with inconsistency
Type I inconsistency among 1985 never smokers	No	105	8	7.6
	Yes	45	5	11.1
	Total	150	13	8.7
Type II inconsistency among 1980 never smokers	No	113	16	14.2
	Yes	42	2	4.8
	Total	155	18	11.6
Type III inconsistency among 1980 current/1985 ex-smokers	No	24	1	4.2
	Yes	22	1	4.5
	Total	46	2	4.3

\*

A2. Married subjects with other adults in household

	Smoker other than spouse in household in 1980	Total subjects	N with inconsistency	% with inconsistency
Type I inconsistency among 1985 never smokers	No	36	4	11.1
	Yes	14	1	7.1
	Total	50	5	10.0
Type II inconsistency among 1980 never smokers	No	37	5	13.5
	Yes	13	0	0.0
	Total	50	5	10.0
Type III inconsistency among 1980 current/1985 ex-smokers	No	12	0	0.0
	Yes	9	1	11.1
	Total	21	1	4.8

\*

Excluding any subjects claiming more smokers than adults in household.
